Summary

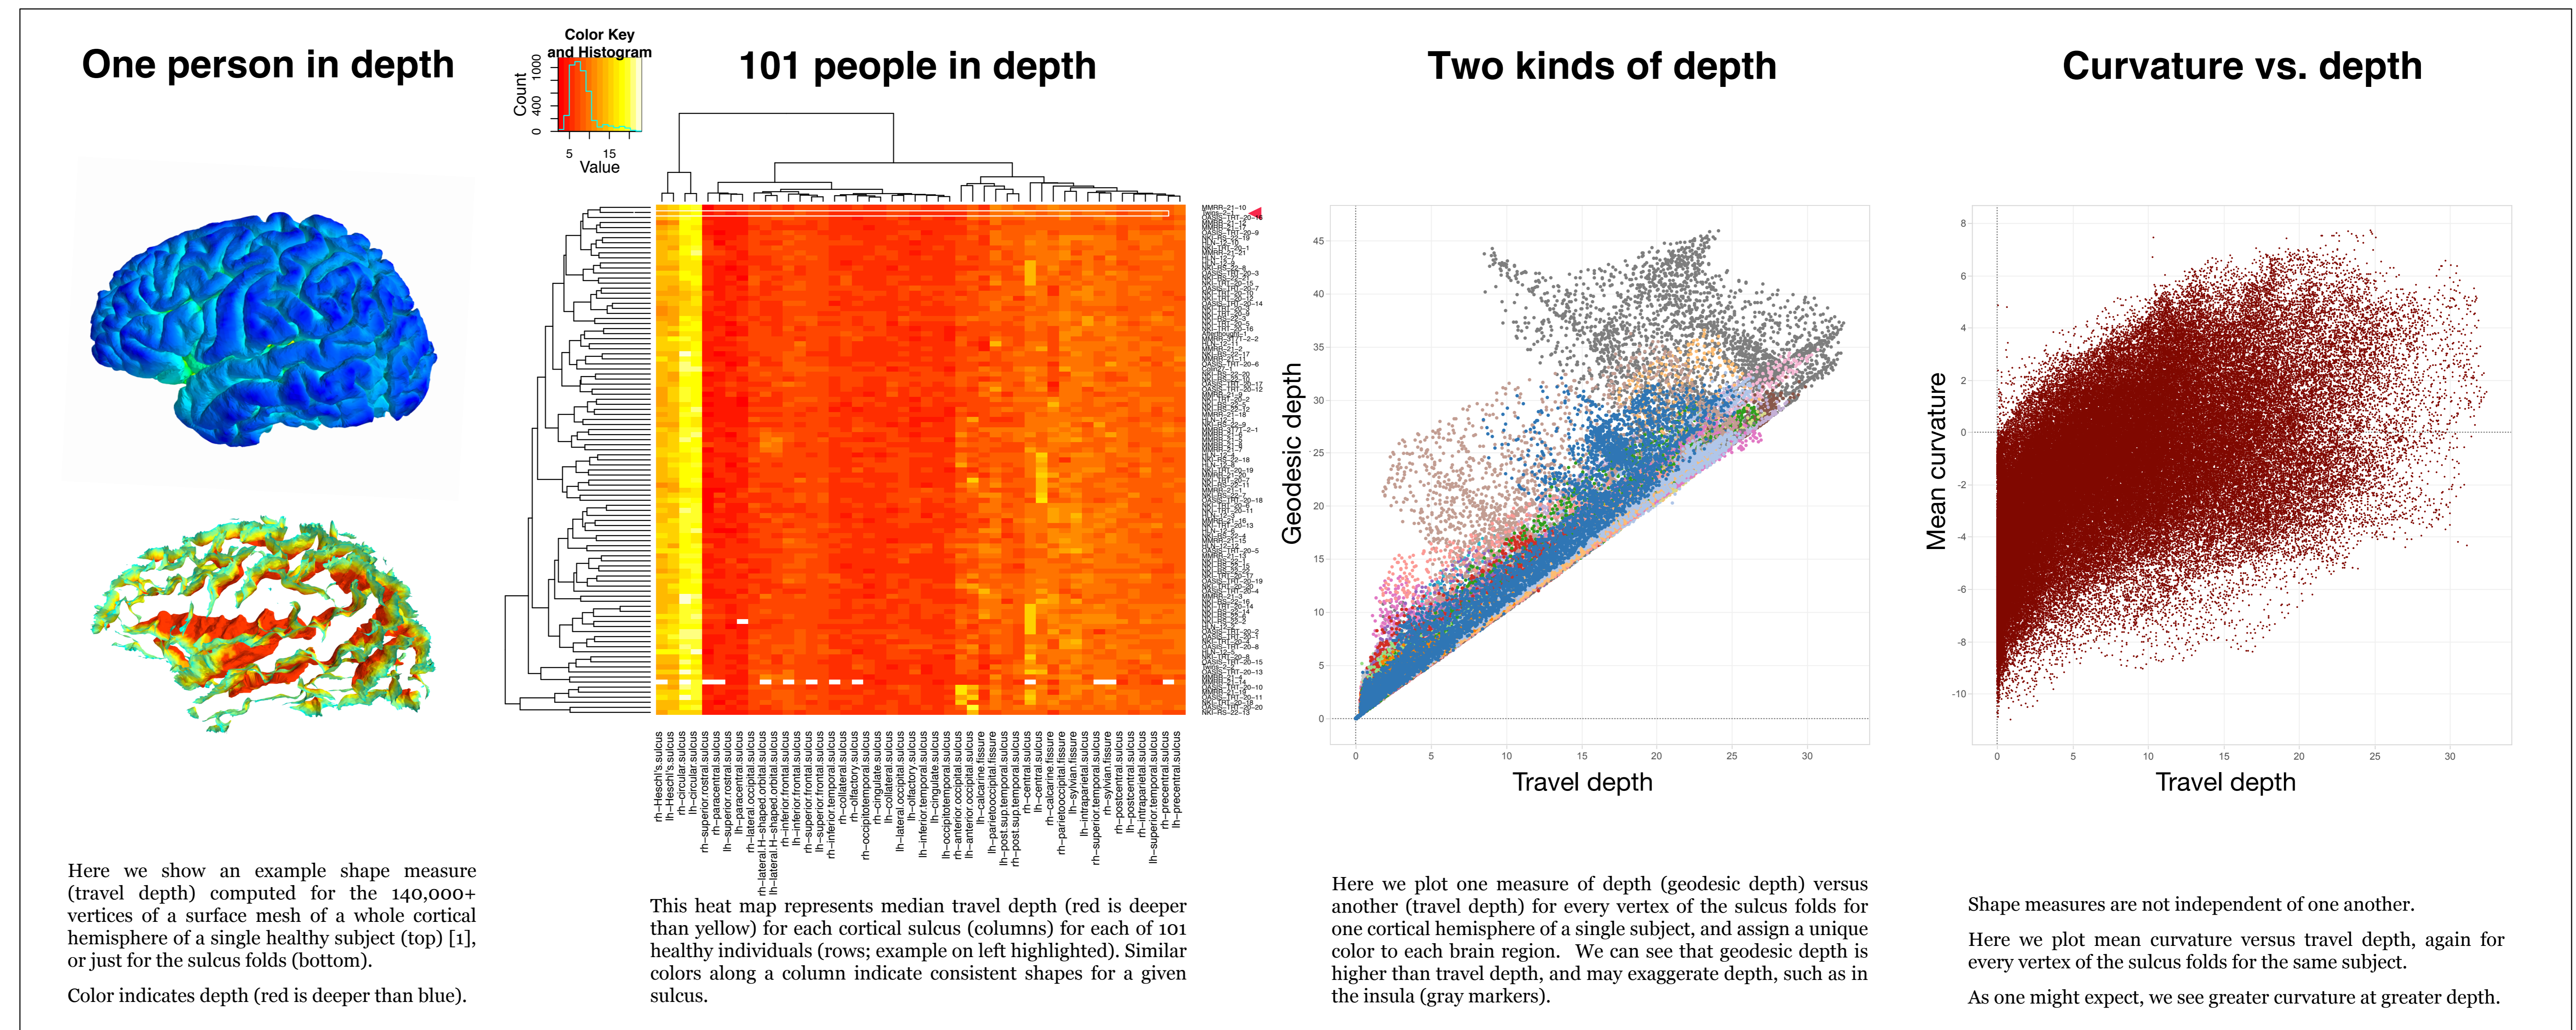

This work constitutes the most detailed shape analysis of human brains ever conducted. The results provide information about the variation in different shape measures computed on MRI-derived brain structures, focusing on healthy brains and brains with Alzheimer's disease (AD). We intend for this effort to drive future comparisons with similarly processed image data of patients with different neuropsychiatric conditions.

Methods

We processed brain MR images from 101 healthy [1] and hundreds of ADNI participants [2] ($N_{AD}=126$, $N_{HC}=199$) by FreeSurfer [3] and ANTs [4]. Mindboggle [5] extracted labeled regions and sulci and measured their shapes: area, thickness, volume, curvature, depth, Laplace-Beltrami spectra, and Zernike moments.

To assess the importance of subject and hemisphere, we fitted a linear mixed model for each shape measure and brain region. To select top structures implicated in AD, we used the average of the ranks of the following tests: (1) Kolmogorov-Smirnov test to see if there was a difference between distributions at baseline and at 3 years, (2) Correlation of change in shape and change in ADNI-MEM cognitive scores.

Example shape measure

Results

- Care must be taken when comparing differently defined shape measures.
- For all shapes and regions, most of the variability is concentrated in the residual (not the hemisphere or individual).
- AD and healthy control brains have similar shape statistical summaries.
- After a 3-year interval, ADNI-MEM scores are estimated best by changes in volume, thickness, curvature in various regions.

Next steps

We have generated data to do the following:

- ➔ Include all covariates and shape measures.
- ➔ Include a volume analysis of non-cortical regions.
- ➔ Look at interactions among shape measures.
- ➔ Compare shapes of FreeSurfer vs. ANTs labels.
- ➔ Compare shapes of automated vs. manual labels.

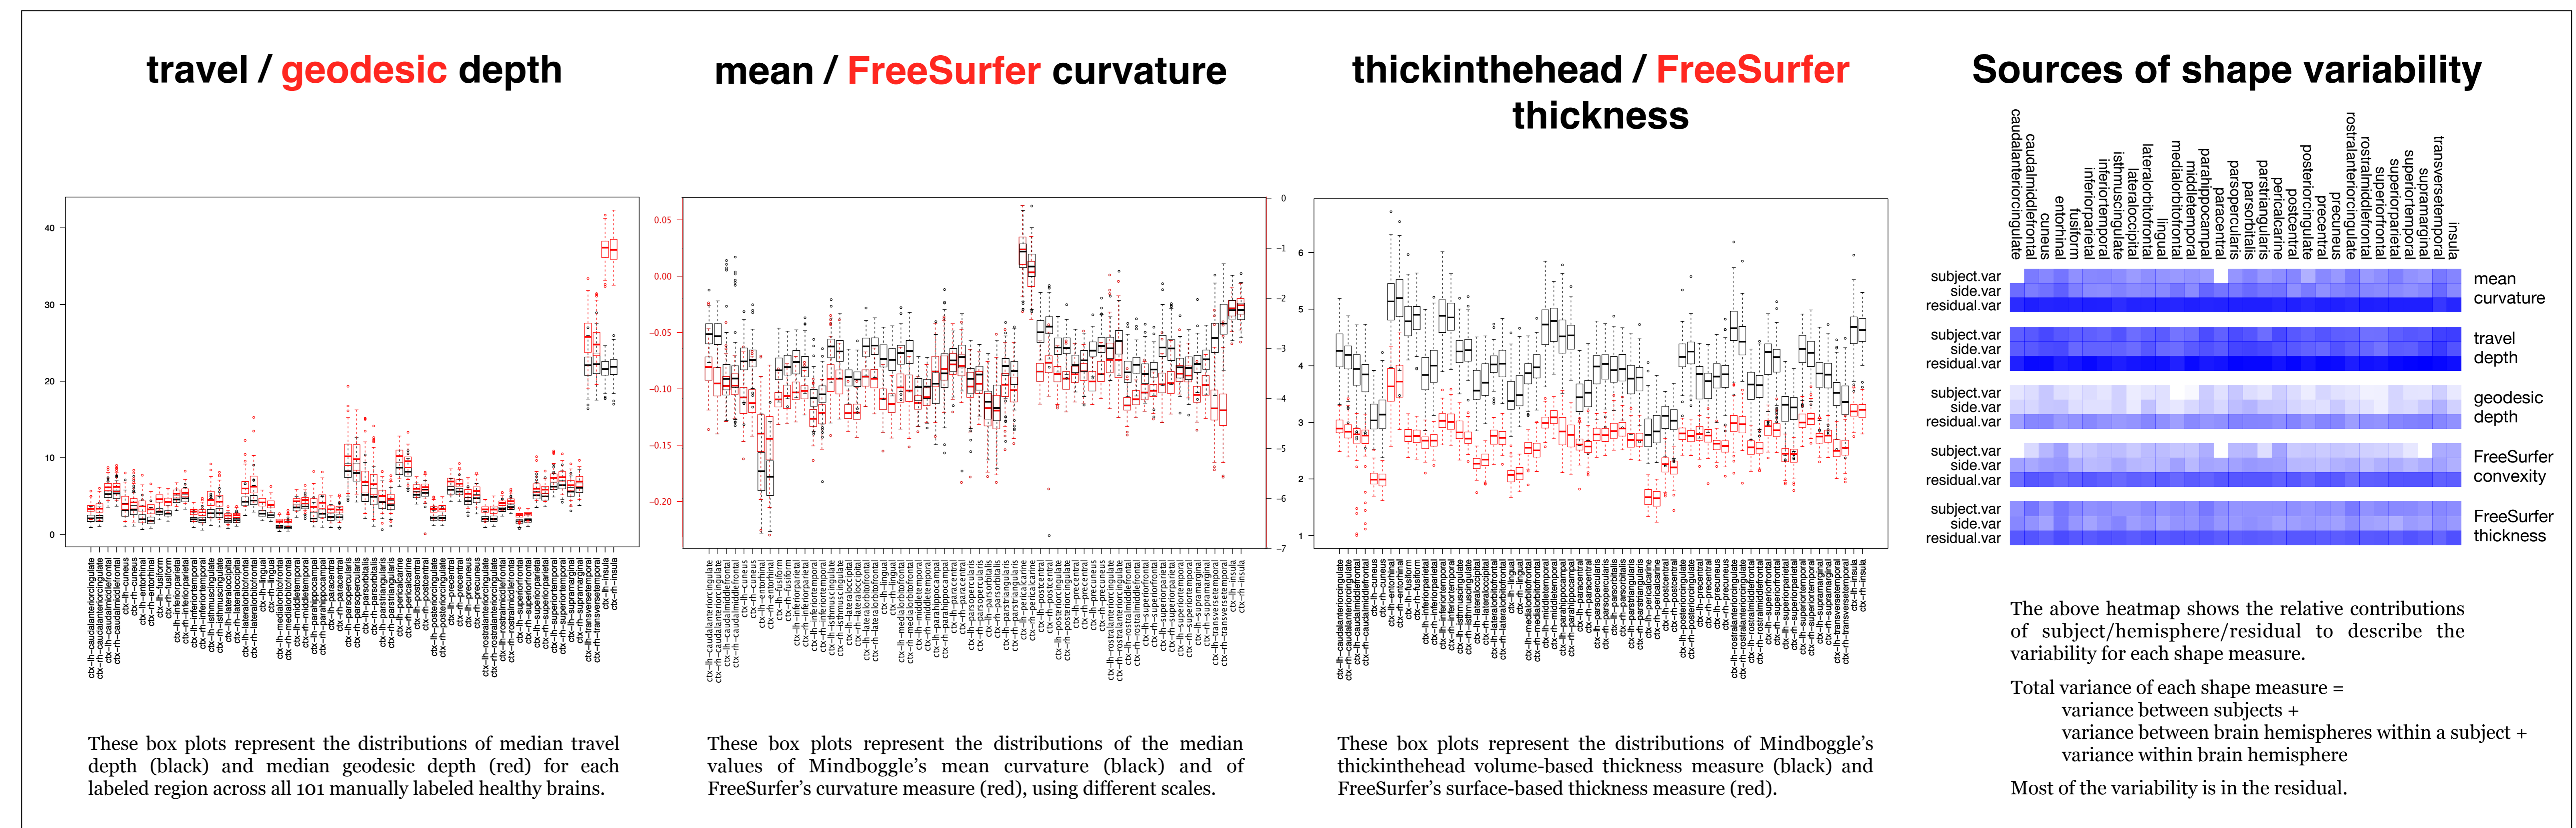

We will also try to infer the heritability of brain shape variation, by analyzing MRI data from monozygotic and dizygotic twins, using data from the Human Connectome Project [6].

Acknowledgments and References

This work was funded by the NIMH R01 grant MH084029. ADNI investigators provided data but did not participate in the analysis or writing of this report.
